THE U.S. OF GURARE IN ARROTHESIA AND FOR OFFICE GLINICAL PURPOSES.
By Harold P. Griffith. N.D.

Read before the Montreal Mediqu-Chirurgical Society, April 2, 1945.
(From the Department of Amesthesia, Homocopathic Hospital of Montreal.)

If anyone had suggested a few years ago that I should present a paper on the clinical use of Gurars I would have been inclined to laugh, for to most of us curars has always been a fabulous poison veguely connected with south american Indians and detective nevels, useful in the physiological laboratory, but far removed from the realm of practical therapouties. Revertheless I have now to report its administration to sixty patients under general anesthesia, and others have used it hundreds of times in various conditions.

Curere has long been known to science - in fact the earliest reference
to its use is in Hakluyt's description of Sir Walter Haleigh's voyage up the
Orinoce in 1895, when even then the Indians were using it as an arrow poison. In
1814 Watterton and Brodie observed that asphysic from respiratory paralysic was
the cause of death in curere poisoning, and in 1840 claude Bernard (1) confirmed
this observation in a series of physiological experiments which have become fomous.
But the modern history of curere, or what one might call the "civilisation" of
the drug, dates only from 1988 when Richard C. Gill, an American who had lived for
many years on the edge of the upper Amazonian jungle of Boundor, and who had himself
just recovered from an attack of special paralysis, led on expedition into this
Bouth American wilderness in the hope that he might obtain a sufficient quantity
of curere and knowledge of its manufacture to make possible its use in exienticie
medicine as a treatment for special disease. In his book "white water and plack
Hagio," Gill (2) tells most interestingly of the difficulties, deagers and final

success of his quest. Curare, which enoug the indises is known as "the flying death," is the most secred and mystifying of all the strange drugs in the primitive pharmacopoon. Its secrets have been for contarios carefully guarded by the witch doctors who make it, and for this reason any accurate information about its origin and its ingredients has been most difficult to obtain. Nevertheless, Gill returned to civilization with a large supply of the crude drug, a detailed history of its menufacture, and with botanical samples of over forty plents which the Indians use in making various kinds of grade carare. Through the co-operation of the Research Laboratories of R.H. Squibb and gone, and Professor A.R. Heintyre of the University of Hebraska, this crude curare was subjected to its first really thorough pharmacological study. The so-called "true curare substance" was separated from various other toxic ingredients which are present in the Indians' arrow poison, and after extensive enimal experimentation a product was obtained which second safe for human trial. This substance was offered to the medical profession for experimental study under the name of "Inteceptrin." (Extract of Emeuthenticated Curare. Southb.)

"Intocontrin" in order to minimise the tremmatic effects of the violent muscular contraction in patients undergoing Hetrasol shock therapy for various paychietric disorders. He (3) and others (4) have reported after many hundred injections that this preparation of curere is harmless to the patient, and extremely valuable in preventing the fractures which formarly resulted rather frequently from shock therapy. A recent report in the Callada Journal by Hr. J.A. Cumins (5) tells of his experience with curere at the Ontario Heapital, Healiton; and at the Verdum Protestant Heapital, Mentreal, curere is being used to modify the effects of electric shock convalsions.

In June. 1940. Dr. LaH. Wright of RaR. Squibb & Sons of How York told me of this new work with oursre and remarked how nice it would be if we could use some of it in anesthesia to relax the muscles of our patients any time they got a little too teuse. I agreed that such an effect is often to be desired but was too horrified at the old poisonous regutation of curare to be seriously interested. I met Er. Fright again in October, 1941, and asked him how he was getting on with curare is anesthesia. He said he still thought the idea was airight but that so far as he know no one had tried it. I thought I'd better not pass up a good thing any longer, so Dr. Wright kindly sent me some amountes of "Intocostrin" and in January, 1942, we began using it in the operating room of the Momos opathic Hospital of Mon treal. We administered the drug intravenously to patients under general amosthesia, and found that it acts quickly, producing in less than a minute a dramatic and complete relaxation of the skeletal massles. Even under the most favorable diroumstances, and with every general amesthetic agent, occasions do arise when it seems impossible to get the patient sufficiently relaxed to make an upper abdominal exploration or to close a friable peritoneum. To have a drug at hand which will give the patient at these critical moments occplote relaxation, uniformly, quickly and hermlessly, has seemed to us a blessing to both surgeon and amesthetist.

nervous impulses to muscle, this interruption taking place at the termination of the nerve fibres at the muscle colls, and probably consists in a neutralization of the acetylcholine reaction which is the fundamental neuro-muscular stimulation mechanism. When a drug having a pure curere action is introduced intravenously it very rapidly produces a paralysis involving skeletal muscles of which in practice the disphragm and intercostals are the last to be affected. In moderate doses there is apparently no effect on cardiac or involuntary muscle. The drug

trensient. In our experience the effect is usually observed within a few seconds, attains its maximum in about five mirates and does not last longer than fifteen or twenty minutes. There is a good deal of individual variation in patients as to the duration of effect, and this depends also to some extent on the depth of amesthesis present. Curare affects only the neuro-muscular junction and it is in no sense an amesthesis agent. Therefore, we do not recommend its use to prolong the effect of spinal amesthesis unless the patient is heavily codated or a general amesthetic is used in combination with the spinal. In two patients we repeated the injection during the same operation and obtained relaxation after each injection without harmful effect. There is some evidence, however, from animal experimentation that the drug may have some cumulative action, so we feel that in anesthesis it should not be repeated indiscriminately but should be used only to overcome some critical situation, and subsequent muscular relaxation should be maintained by the use of the anesthetic agent itself.

Interestrin is marketed in 5 cc. vials of a sterile aqueous solution which contains 20 mg. of the pure curare substance to each oc. To have found that 5 cc. (or 100 mg. of curare substance) is an adequate dose for the average adult. We make the injection intravenously, and quite rapidly, and have had no case of thrombosis or other local reaction. This dose is rather larger than that usually used by psychiatrists, but we feel that the conditions under which we work with curare in surgery are much safer than those of most psychiatric institutions. In the operating room we have the patient already asleep under the care of an experienced amenthatist and with adequate exprenation, a free airway and every facility at hand for the proper control of respiration. In none of our patients have we observed any appreciable effect on pulse or blood pressure. Respiratory degression and even generation of respiration occurred in a few cases.

but we are so accustomed to artificial control of the respiration in patients under modern anesthesis technique that such an effect doesn't verry us at all, and there has never been any heraful post-operative disturbance. Almost all our patients have been under syclopropane amesthesis, but a few received nitrous oxide and other. One young man undergoing cholesystestomy for a very severe acute hasmorphagic pancreatitis was given open other with most unsatisfactory abdominal relexation. He was given 5 ca. Intercettin and immediate relaxation ensued but there was also constitue of respiration. An endotracheal tube was introduced and exesthesis continued with controlled respiration and cyclopropane and oxygen. I'm gled to say that in spite of the other, the curare and the pancreatitie, he subsequently recovered.

apparently bears the closest resemblance to a true physiological antidote of curare. In patients with speathenic gravis it note to inhibit the choline esterase and to restore the acetylcholine preponderance at the syo-neural junction. (6) Since curare action is very similar to mysethenia gravis, prostigmin should quickly counteract the curare effect. For this reason an empoule of prestigmin should always be available when curare is given, although in our gapes we have not had to use it.

results obtained when an adequate dose of our are was given that in July, 1962,

Dr. Enid Johnson and I published a preliminary report on "The Use of Curare in

General Amesthesia." (?) This has led to further clinical trial by anesthetists

in the United States and Camada, and many have written me that they believe this

to be an important new approach to the problem of suscular relaxation in amenthesia.

Dr. S.C. Gullen, of the University of Iowa, has recently published (8) a report

on the use of curare in 250 patients under inhalation anesthesia. It is gratifying

that his work has confirmed our findings, and he says that surgeons with whom he works are enthusiastic about the results obtained. His technique of administration has been seembat similar to ours, except that he gives the curare now more or less routinely before the paritonoum is opened in patients with whom he expects to have difficulty in securing relogation. He has administered the drug in fractionally repeated doses to a number of patients with satisfactory result in prolonging the period of complete amequiar relogation. He feels that curare is much more depressing to the respiration in patients under other than under eyelopropene, but in every case artificial respiration by menual compression of the breathing bag was all that was necessary to restore the patient to normal breathing.

During recent months we have not used oursre very frequently and our total series has grown only to sixty cases simply becomes we were satisfied with its officery and wished to keep it for cases in which it was really needed. Inadequate relexation is not a frequent complication with modern anesthesia technique and the good amouthatist should not need curare every day or even every week. It is still a potentially desgerous drug, and I wouldn't like to see it used indiscriminately by unskilled anosthetists simply because they were too inefficient to obtain miscular relogation by ordinary anesthetic procedures. Also, one should not expect too such of the drug. According to our present knowledge, carare is simply a powerful but short seting adjuvant to smeathetic agents, to be used in an unconscious patient to tide one over an emergency situation where complete relegation is demanded. We have found it to be required most frequently in strong, young adults who may be just as resistant to any enesthetic agent as are some men to the effects of whisky. I don't recommend it as on aid during the excitement of a difficult induction, or for a short procedure such as the reduction of a dislocation, because in these cases such an agent

as intravenous pentothal may do the work perfectly satisfactorily and probably more safely.

So such for oursre in emesthesis and in paychistry. One might speculate upon other possible fields for clinical use. Perhaps we may find it of value in the treatment of any conditions where there is too violent musqular contraction or too perciatent muscular spage. Gill had hoped that it would prove an effective treatment for the various forms of speatic paralysis. This dress has come true to a certain degree, and Barman (9) and others are now advocating the use of curare and crythroidine hydrochloride for spastic and dystonic states. An obstacle to the effective use of our are in the treatment of these conditions is that its action is flooting and cannot be long maintained. However, since the treatment of spectic paralysis is concerned largely with the re-aducation of smedies and nerves, a drug such as curare, which will give even temporary relogation to those who are in a state of constant spass, has proved to be a great help in belstering the patients' morele and giving them confidence and hope. Guilen reports a case of totams successfully controlled by repeated curare injections; and it might be used for the control of colemptic and other forms of convalsions in unconscious patients providing that oxygon and means of ertificial respiration were always at head.

This, then, is the rementic story of the transformation of a drug from the kettles and gourds of Indian witch doctors to the biological standardisation and storile ampoules of modern medicine. What chapters of the story remain to be told only time will tell, but I think that enough has already been revealed to assure for curare a definitely upsful place in our pharmacoposa.
