

Additional for Routine.

1 One more portion of the cretaceous of the south bed of Red Mountain (at Webster on the road northern lot 102). There has been traced of three miles in a direct line across the County and except a portion of the farther end which becomes mixed with granite veins, of excellent quality. At one place where it is well exposed it shows feet of excellent red sand of probably Uman's something like this. This thickness stands out. About two miles of this are in the area taken but I deem the whole the appropriate name published the Mining rights in favor of the south of the agreement as far as the red extends. ^{The south is plainly the} ^{of the blue is very fine}

2 On the Specular vein very satisfactory samples have been made in different parts of the vein area and more especially near its center. Here at the distant places the thicknesses seem to be constant. The vein is 12 feet wide and at one place is wholly specular one of the finest quality. The other name 'red' is of good quality. The vein is traversed by surface indicating to the limits of the area and has been partially un-
covered quite to be true.

3 No farther work has been done by the Survey but its course has been traced on the surface and by an or certain arrangements can be made with proper full tests will be made.
